8.1 Introduction

A large number of the files in a typical filesystem are *text files*. Text files contain simply text, no formatting features that you might see in a word processing file.

Because there are so many of these files on a typical Linux system, a great number of commands exist to help users manipulate text files. There are commands to both view and modify these files in various ways.

In addition, there are features available for the shell to control the output of commands, so instead of having the output placed in the terminal window, the output can be *redirected* into another file or another command. These redirection features provide users with a much more flexible and powerful environment to work within.

Searching and Extracting Data from Files

- Weight: 4
- Description: Search and extract from files in the home directory.
- Key Knowledge Areas:
 - Command line pipes
 - I/O re-direction
 - Partial POSIX Regular Expressions (.,[],*,?)
- The following is a partial list of the used files, terms, and utilities:
 - find
 - grep
 - less
 - head, tail
 - sort
 - cut
 - WC
- Thing that are nice to know:
 - Partial POSIX Basic Regular Expressions ([^], ^, \$)
 - Partial POSIX Extended Regular Expressions (+,(),|)
 - xargs

8.3 Command Line Pipes

Previous chapters discussed how to use individual commands to perform actions on the operating system, including how to create/move/delete files and move around the system. Typically, when a command has output or generates an error, the output is displayed to the screen; however, this does not have to be the case.

The *pipe* (|) character can be used to send the output of one command to another. Instead of being printed to the screen, the output of one command becomes input for the next command. This can be a powerful tool, especially when looking for specific data; *piping* is often used to refine the results of an initial command.

The head and tail commands will be used in many examples below to illustrate the use of pipes. These commands can be used to display only the first few or last few lines of a file (or, when used with a pipe, the output of a previous command).

By default the head and tail commands will display ten lines. For example, the following command will display the first ten lines of the /etc/sysctl.conf file:

📧 sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
<pre>[sysadmin@localhost ~]\$ head /etc/sysctl.conf # Kernel sysctl configuration file for Red Hat Linux # # For binary values, 0 is disabled, 1 is enabled. See sysctl(8) and # sysctl.conf(5) for more details.</pre>		^
<pre># Controls IP packet forwarding net.ipv4.ip_forward = 0</pre>		
<pre># Controls source route verification net.ipv4.conf.default.rp filter = 1 [sysadmin@localhost ~]\$</pre>		

In the next example, the last ten lines of the file will be displayed:

sysadmin@localhost:~	_ 0	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ tail /etc/sysctl.conf kernel.msgmnb = 65536		^
# Controls the maximum size of a message, in bytes kernel.msgmax = 65536		
# Controls the maximum shared segment size, in bytes kernel.shmmax = 4294967295		
# Controls the maximum number of shared memory segments, in pages kernel.shmall = 268435456 [sysadmin@localhost ~]\$		

The pipe character will allow users to utilize these commands not only on files, but on the output of other commands. This can be useful when listing a large directory, for example the /etc directory:

2				sysa	admin@localhost:~		-	×
<u>F</u> ile	<u>E</u> dit	View	<u>S</u> earch	Terminal	<u>H</u> elp			
fstat gai.c gconf gcryp gdm ggz.m ghost	o conf f ot nodulo tscri	es.d pt		openct openld opt Packag pam.d pango passwd	.conf ap eKit	<pre>sysctl.conf system-release system-release-cpe terminfo tpvmlp.conf Trolltech.conf udev updatedb_conf</pre>		<
group group group grub gshac gshac gshac gssap gtk-2	conf low low- bi_mee 2.0	ch.con	f	passwd pbm2pp pcmcia pinfor pki plymou pm pm-uti pnm2pp	- a.conf c th ls-hd-apm-restore.conf a.conf	vimrc virc vmware-tools warnquota.conf wgetrc wpa_supplicant X11 xdg		
host hosts hosts hosts hp htdig [sysa	conf .all .den .den	ow y @local	host ~]:	portre postfi ppp prelin prelin	serve x k.cache k.conf	xml yp.conf yum yum.conf yum.repos.d		

If you look at the output of the previous command, you will note that first filename is fstab. But there are other files listed "above" that can only be viewed if the user uses the scroll bar. What if you just wanted to list the first few files of the /etc directory?

Instead of displaying the full output of the above command, piping it to the head command will display only the first ten lines:

📧 sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ ls /etc head abrt acpi adjtime akonadi aliases aliases.db alsa alternatives anacrontab anthy-conf [sysadmin@localhost ~]\$ ■		

The full output of the ls command is passed to the head command by the shell instead of being printed to the screen. The head command takes this output (from Is) as "input data" and the output of head is then printed to the screen.

Multiple pipes can be used consecutively to link multiple commands together. If three commands are piped together, the first command's output is passed to the second command. The output of the second command is then passed to the third command. The output of the third command would then be printed to the screen.

It is important to carefully choose the order in which commands are piped, as the third command will only see input from the output of the second. The examples below illustrate this using the nl command. In the first example, the nl command is used to number the lines of the output of a previous command:

Σ	sysadmin@localhost:~	_ 🗆 🗙
<u>File Edit View Search Terr</u>	ninal <u>H</u> elp	
[sysadmin@localhost ~]\$ ls	-l /etc/ppp nl	^
2 -rw 1 root	root 78 Aug 22 2010 chap-secrets	
3 -rwxr-xr-x. 1 root	root 386 Apr 27 2012 ip-down	
4 -rwxr-xr-x. 1 root	root 3262 Apr 27 2012 ip-down.ipv6to4	
5 -rwxr-xr-x. 1 root	root 430 Apr 27 2012 ip-up	
6 -rwxr-xr-x. 1 root	root 6517 Apr 27 2012 ip-up.ipv6to4	
7 -rwxr-xr-x. 1 root	root 1687 Apr 27 2012 ipv6-down	
8 -rwxr-xr-x. 1 root	root 3196 Apr 27 2012 ipv6-up	
9 -rw-rr 1 root	root 5 Aug 22 2010 options	
10 -rw 1 root	root 77 Aug 22 2010 pap-secrets	
11 drwxr-xr-x. 2 root	root 4096 Jun 22 2012 peers	
[sysadmin@localhost ~]\$		

In the next example, note that the ls command is executed first and its output is sent to the nl command, numbering all of the lines from the output of the ls command. Then the tail command is executed, displaying the last five lines from the output of the nl command:

🖭 sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ ls -l /etc/ppp nl tail -5		^
7 -rwxr-xr-x. 1 root root 1687 Apr 27 2012 ipv6-down		
8 -rwxr-xr-x. 1 root root 3196 Apr 27 2012 ipv6-up		
9 -rw-rr 1 root root 5 Aug 22 2010 options		
10 -rw 1 root root 77 Aug 22 2010 pap-secrets		
11 drwxr-xr-x. 2 root root 4096 Jun 22 2012 peers		
[sysadmin@localhost ~]\$		

Compare the output above with the next example:

Σ			sysadmin	i@loca	lhost:~	_ 0 ×
<u>F</u> ile <u>E</u> o	lit <u>V</u> iew <u>S</u> ear	rch <u>T</u> erm	ninal <u>H</u> elp			
[sysadm	in@localhost	~]\$ ls	-l /etc/p	pp t	ail -5 nl	^
1	-rwxr-xr-x.	1 root	root 1687	Apr 2	27 2012 ipv6-down	
2	-rwxr-xr-x.	1 root	root 3196	Apr 2	7 2012 ipv6-up	
3	-rw-rr	1 root	root 5	Aug 2	2 2010 options	
4	-rw	1 root	root 77	Aug 2	2 2010 pap-secrets	
5	drwxr-xr-x.	2 root	root 4096	Jun 2	2 2012 peers	
[sysadm	in@localhost	~]\$			-	

Notice how the line numbers are different. Why is this?

In the second example, the output of the ls command is first sent to the tail command which "grabs" only the last five lines of the output. Then the tail command sends those five lines to the nl command, which numbers them 1-5.

Pipes can be powerful, but it is important to consider how commands are piped to ensure that the desired output is displayed.

8.4 I/O Redirection

Input/Output (I/O) redirection allows for command line information to be passed to different *streams*. Before discussing redirection, it is important to understand standard streams.

8.4.1 STDIN

Standard input, or STDIN, is information entered normally by the user via the keyboard. When a command prompts the shell for data, the shell provides the user with the ability to type commands that, in turn, are sent to the command as STDIN.

8.4.2 STDOUT

Standard output, or STDOUT, is the normal output of commands. When a command functions correctly (without errors) the output it produces is called STDOUT. By default, STDOUT is displayed in the terminal window (screen) where the command is executing.

8.4.3 STDERR

Standard error, or STDERR, are error messages generated by commands. By default, STDERR is displayed in the terminal window (screen) where the command is executing.

I/O redirection allows the user to redirect STDIN so data comes from a file and STDOUT/STDERR so output goes to a file. Redirection is achieved by using the arrow characters: (<) and (>).

8.4.4 Redirecting STDOUT

STDOUT can be directed to files. To begin, observe the output of the following command which will display to the screen:

Σ	sysadmin@localhost:~	-	x
<u>F</u> ile	<u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sys Line [sys	admin@localhost ~]\$ echo "Line 1" 1 admin@localhost ~]\$		^

Using the > character the output can be redirected to a file:

sysadmin@localhost:~	_ 🗆 ×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp	
[sysadmin@localhost ~]\$ echo "Line 1" > example.txt [sysadmin@localhost ~]\$ ls	^
Desktop Downloads Music Public Templates	
[sysadmin@localhost ~]\$ cat example.txt	
Line 1 [sysadmin@localhost ~]\$	

This command displays no output, because STDOUT was sent to the file example.txt instead of the screen. You can see the new file with the output of the ls command. The newly-created file contains the output of the echo command when the file is viewed with the cat command.

It is important to realize that the single arrow will overwrite any contents of an existing file:

sysadmin@localhost:~	_	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ cat example.txt		^
Line 1 [sysadmin@localhost ~]\$ echo "New line 1" > example.txt [sysadmin@localhost ~]\$ cat example.txt New line 1 [sysadmin@localhost ~]\$		

The original contents of the file are gone, replaced with the output of the new echo command.

It is also possible to preserve the contents of an existing file by appending to it. Use "double arrow" (>>) to append to a file instead of overwriting it:

🗷 sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ cat example.txt New line 1		^
[sysadmin@localhost ~]\$ echo "Another line" >> example.txt [sysadmin@localhost ~]\$ cat example.txt New line 1		
Another line [sysadmin@localhost ~]\$		

Instead of being overwritten, the output of the most recent echo command is added to the bottom of the file.

8.4.5 Redirecting STDERR

STDERR can be redirected in a similar fashion to STDOUT. STDOUT is also known as *stream* (or*channel*) #1. STDERR is assigned stream #2.

When using arrows to redirect, stream #1 is assumed unless another stream is specified. Thus, stream #2 must be specified when redirecting STDERR.

To demonstrate redirecting STDERR, first observe the following command which will produce an error because the specified directory does not exist:

sysadmin@localhost:~	_	• •
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ ls /fake ls: cannot access /fake: No such file or directory [sysadmin@localhost ~]\$		

Note that there is nothing in the example above that implies that the output is STDERR. The output is clearly an error message, but how could you tell that it is being sent to STDERR? One easy way to determine this is to redirect STDOUT:

2	sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> di	t <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmi ls: cann [sysadmi	n@localhost ~]\$ ls /fake > output.txt ot access /fake: No such file or directory n@localhost ~]\$		^

In the example above, STDOUT was redirected to the output.txt file. So, the output that is displayed can't be STDOUT because it would have been placed in the output.txt file. Because all command output goes either to STDOUT or STDERR, the output displayed above must be STDERR.

The STDERR output of a command can be sent to a file:

sysadmin@localhost:~	_	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ ls /fake 2> error.txt [sysadmin@localhost ~]\$ more error.txt ls: cannot access /fake: No such file or directory [sysadmin@localhost ~]\$		<

In the command above, the 2> indicates that all error messages should be sent to the file error.txt.

8.4.6 Redirecting Multiple Streams

It is possible to direct both the STDOUT and STDERR of a command at the same time. The following command will produce both STDOUT and STDERR because one of the specified directories exists and the other does not:

2	sysadmin@localhost:~							
<u>File Edit Vie</u>	w <u>S</u> earch <u>T</u> ermina	l <u>H</u> elp						
[sysadmin@loc ls: cannot ac /etc/ppp:	alhost ~]\$ ls /fa cess /fake: No su	ke /etc/ppp ch file or dire	ctory					^
chap-secrets	ip-down.ipv6to4 ip-up	ip-up.ipv6to4 ipv6-down	<pre>ipv6-up options</pre>	pap-secrets				
[sysadmin@loc	alhost ~]\$		0001000	Peer e				

If only the STDOUT is sent to a file, STDERR will still be printed to the screen:

```
Σ
                           sysadmin@localhost:~
                                                                           _ 🗆 🗙
File Edit View Search Terminal Help
[sysadmin@localhost ~]$ ls /fake /etc/ppp > example.txt
                                                                                 ^
ls: cannot access /fake: No such file or directory
[sysadmin@localhost ~]$ cat example.txt
/etc/ppp:
chap-secrets
ip-down
ip-down.ipv6to4
ip-up
ip-up.ipv6to4
ipv6-down
ipv6-up
options
pap-secrets
peers
[sysadmin@localhost ~]$
```

If only the STDERR is sent to a file, STDOUT will still be printed to the screen:

Σ	sys	admin@localho	st:~		-	×
<u>File Edit V</u> iew	<u>Search</u> <u>T</u> erminal	<u>H</u> elp				
[sysadmin@localh /etc/ppp: chap-secrets ip ip-down ip [sysadmin@localh ls: cannot acces [sysadmin@localh	nost ~]\$ ls /fak p-down.ipv6to4 p-up nost ~]\$ cat ern ss /fake: No suc nost ~]\$ ■	<pre>ke /etc/ppp 2> ip-up.ipv6to4 ipv6-down ror.txt ch file or dire</pre>	error.txt ipv6-up options ctory	pap-secrets peers		^

Both STDOUT and STDERR can be sent to a file by using &>, a character set that means "both 1> and 2>":

🗉 sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
<pre>[sysadmin@localhost ~]\$ ls /fake /etc/ppp &> all.txt [sysadmin@localhost ~]\$ cat all.txt ls: cannot access /fake: No such file or directory /etc/ppp: chap-secrets ip-down ip-down.ipv6to4 ip-up ip-up.ipv6to4 ipv6-down ipv6-up options pap-secrets peers [sysadmin@localhost ~]\$</pre>		

Note that when you use &>, the output appears in the file with all of the STDERR messages at the top and all of the STDOUT messages below all STDERR messages:

sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
<pre>[sysadmin@localhost ~]\$ ls /fake /etc/ppp /junk /etc/sound &> all.txt [sysadmin@localhost ~]\$ cat all.txt ls: cannot access /fake: No such file or directory ls: cannot access /junk: No such file or directory /etc/ppp: chap-secrets ip-down ip-down.ipv6to4 ip-up ip-up.ipv6to4 ipv6-down ipv6-up options pap-secrets peers</pre>		~
/etc/sound: events [sysadmin@localhost ~]\$		

If you don't want STDERR and STDOUT to both go to the same file, they can be redirected to different files by using both > and 2>. For example:

```
Σ
                           sysadmin@localhost:~
                                                                           File Edit View Search Terminal Help
[sysadmin@localhost ~]$ rm error.txt example.txt
                                                                                ~
[sysadmin@localhost ~]$ ls
all.txt Documents Music
                             Public
                                        Videos
Desktop Downloads Pictures Templates
[sysadmin@localhost ~]$ ls /fake /etc/ppp > example.txt 2> error.txt
[sysadmin@localhost ~]$ ls
all.txt Documents error.txt
                                Music
                                          Public
                                                     Videos
Desktop Downloads example.txt Pictures Templates
[sysadmin@localhost ~]$ cat error.txt
ls: cannot access /fake: No such file or directory
[sysadmin@localhost ~]$ cat example.txt
/etc/ppp:
chap-secrets
ip-down
ip-down.ipv6to4
ip-up
ip-up.ipv6to4
ipv6-down
ipv6-up
options
pap-secrets
peers
[sysadmin@localhost ~]$
```

The order the streams are specified in does not matter.

8.4.7 Redirecting STDIN

The concept of redirecting STDIN is a difficult one because it is more difficult to understand *why*you would want to redirect STDIN. With STDOUT and STDERR, the answer to *why* is fairly easy: because sometimes you want to store the output into a file for future use.

Most Linux users end up redirecting STDOUT routinely, STDERR on occasion and STDIN...well, very rarely. There are very few commands that require you to redirect STDIN because with most commands if you want to read data from a file into a command, you can just specify the filename as an argument to the command. The command will then look into the file.

For some commands, if you don't specify a filename as an argument, they will revert to using STDIN to get data. For example, consider the following cat command:

Σ	sysadmin@localhost:~								-	×		
<u>F</u> ile	<u>E</u> dit	<u>V</u> iew	<u>S</u> earch	<u>T</u> erminal	<u>H</u> elp							
[sysa hello how a how a goodb goodb [sysa	admin@ are yo are yo are yo ye ye admin@	local u? u? local	host ~]\$ host ~]\$	\$ cat								<

In the example above, the cat command wasn't provided a filename as an argument. So, it asked for the data to display on the screen from SDTIN. The user typed "hello" and then the cat command displayed "hello" on the screen. Perhaps this is useful for lonely people, but not really a good use of the cat command.

However, perhaps if the output of the cat command were redirected to a file, then this method could be used either to add to an existing file or to place text into a new file:

Σ	sysadmin@localhost:~	-	×
<u>File Edit View Sear</u>	ch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost Hello How are you? Goodbye [sysadmin@localhost Hello How are you? Goodbye [sysadmin@localhost	~]\$ cat > new.txt ~]\$ cat new.txt ~]\$		^

While the previous example demonstrates another advantage of redirecting STDOUT, it doesn't address why or how STDIN can be directed. To understand this, first consider a new command called tr. This command will take a set of characters and translate them into another set of characters.

For example, suppose you wanted to capitalize a line of text. You could use the tr command as follows:

Σ	sysadmin@localhost:~	_	×
<u>F</u> ile	<u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysa watch WATCH [sysa	admin@localhost ~]\$ tr 'a-z' 'A-Z' h how this works H HOW THIS WORKS admin@localhost ~]\$		<

The tr command took the STDIN from the keyboard ("watch how this works") and converted all lower case letters before sending STDOUT to the screen ("WATCH HOW THIS WORKS").

It would seem that a better use of the tr command would be to perform translation on a file, not keyboard input. However, the tr command does not support filename arguments:

sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ more example.txt		^
/etc/ppp:		
chap-secrets		
ip-down		
ip-down.ipv6to4		
ip-up		
ip-up.ipv6to4		
ipv6-down		
1pv6-up		
options		
pap-secrets		
peers		
[sysadmin@localhost ~]\$ tr 'a-z' 'A-Z' example.txt		
tr: extra operand example.txt'		
Try trnelp' for more information.		
[sysadmin@localnost ~]\$		

You can, however, tell the shell to get STDIN from a file instead of from the keyboard by using the < character:

				sysa	admin@l	ocalhost:	~		-	×
<u>F</u> ile	<u>E</u> dit	<u>V</u> iew	<u>S</u> earch	<u>T</u> erminal	<u>H</u> elp					
[sysa /ETC/ CHAP- IP-DO IP-UP IP-UP IPV6- IPV6- OPTIO PAP-S PEERS [sysa	dmin@ (PPP: SECRE WN WN.IP OWN.IP DOWN UP ONS SECRET	localł TS V6TO4 TO4 S localł	nost ~]\$	5 tr 'a-z	' 'A-Z'	< example	e.txt			A

This is fairly rare because most commands do accept filenames as arguments. But, for those that do not, this method could be used to have the shell read from the file instead of relying on the command to have this ability.

One last note: In most cases you probably want to take the resulting output and place it back into another file:

📧 sysadmin@localhost:~	_ 0	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
<pre>[sysadmin@localhost ~]\$ tr 'a-z' 'A-Z' < example.txt > no [sysadmin@localhost ~]\$ more newexample.txt /ETC/PPP: CHAP-SECRETS IP-DOWN IP-DOWN IP-DOWN.IPV6T04 IP-UP IP-UP.IPV6T04 IPV6-DOWN IPV6-UP OPTIONS PAP-SECRETS PEERS [sysadmin@localhost ~]\$</pre>	ewexample.txt	

8.5 Searching for Files Using the Find Command

One of the challenges that users face when working with the filesystem, is trying to recall the location where files are stored. There are thousands of files and hundreds of directories on a typical Linux filesystem, so recalling where these files are located can pose challenges.

Keep in mind that most of the files that you will work with are ones that you create. As a result, you often will be looking in your own home directory to find files. However, sometimes you may need to search in other places on the filesystem to find files created by other users.

The find command is a very powerful tool that you can use to search for files on the filesystem. This command can search for files by name, including using wildcard characters for when you are not certain of the exact filename. Additionally, you can search for files based on file metadata, such as file type, file size and file ownership.

The syntax of the find command is:

```
find [starting directory] [search option] [ search criteria] [result option]
```

A description of all of these components:

Component	Description
[starting directory]	This is where the user specifies where to start searching. The find command will search this directory and all of its subdirectories. If no starting directory is

Component	Description
	provided, then the current directory is used for the starting point.
[search option]	This is where the user specifies an option to determine what sort of metadata to search for; there are options for file name, file size and many other file attributes.
[search criteria]	This is an argument that compliments the search option. For example, if the user uses the option to search for a file name, the search criteria would be the filename.
[result option]	This option is used to specify what action should be taken once the file is found. If no option is provided, the file name will be printed to STDOUT.

8.5.1 Search by File Name

To search for a file by name, use the <u>-name</u> option to the <u>find</u> command:

sysadmin@localhost:~ _	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp	
[sysadmin@localhost ~]\$ find /etc -name hosts	^
find: `/etc/dhcp': Permission denied	
find: `/etc/cups/ssl': Permission denied	
find: `/etc/pki/CA/private': Permission denied	
find: `/etc/pki/rsyslog': Permission denied	
find: `/etc/audisp': Permission denied	
find: `/etc/named': Permission denied	
find: `/etc/lvm/cache': Permission denied	
find: `/etc/lvm/backup': Permission denied	
find: `/etc/lvm/archive': Permission denied	
/etc/hosts	
find: /etc/ntp/crypto': Permission denied	
find: /etc/polkit-1/localauthority': Permission denied	Ξ
find: /etc/sudoers.d': Permission denied	
find: /etc/sssd': Permission denied	
/etc/avahi/hosts	
find: //etc/selinux/targeted/modules/active': Permission denied	
Tind: /etc/audit': Permission denied	
[sysadmin@localhost ~]\$	

Note that two files were found: /etc/hosts and /etc/avahi/hosts. The rest of the output was STDERR messages because the user who ran the command didn't have the permission to access certain subdirectories.

Recall that you can redirect STDERR to a file so you don't need to see these error messages on the screen:

sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ find /etc -name hosts 2> errors.txt /etc/hosts /etc/avahi/hosts [sysadmin@localhost ~]\$		^

While the output is easier to read, there really is no purpose to storing the error messages in the error.txt file. The developers of Linux realized that it would be good to have a "junk file" to send unnecessary data; any file that you send to the /dev/null file is discarded:

🗵 sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ find /etc -name hosts 2> /dev/null /etc/hosts /etc/avahi/hosts [sysadmin@localhost ~]\$		^

8.5.2 Displaying File Detail

It can be useful to obtain file details when using the find command because just the file name itself might not be enough information for you to find the correct file.

For example, there might be seven files named hosts; if you knew that the host file that you needed had been modified recently, then the modification timestamp of the file would be useful to see.

To see these file details, use the -ls option to the find command:

sysadmin@loc	alhost:~	-	
<u>File Edit View Search Terminal H</u> elp			
<pre>[sysadmin@localhost ~]\$ find /etc -name hosts 41 4 -rw-rr 1 root root 6549 4 -rw-rr 1 root root [sysadmin@localhost ~]\$</pre>	-ls 2> /dev/null 158 Jan 12 2010 /etc/hosts 1130 Jul 19 2011 /etc/avahi/hosts		

The first two columns of the output above are the *inode number* of the file and the number of *blocks* that the file is using for storage. Both of these are beyond the scope of the topic at hand. The rest of the columns are typical output of the ls -1 command: file type, permissions, hard link count, user owner, group owner, file size, modification timestamp and file name.

8.5.3 Searching for Files by Size

One of the many useful searching options is the option that allows you to search for files by size. The <u>-size</u> option allows you to search for files that are either larger than or smaller then a specified size as well as search for an exact file size.

When you specify a file size, you can give the size in bytes (c), kilobytes (k), megabytes (M) or gigabytes (G). For example, the following will search for files in the /etc directory structure that are exactly 10 bytes large:

Σ				sys	admin@loc	alhost: [,]	~				-	• ×	
<u>F</u> ile <u>E</u> d	it <u>V</u> iew	<u>S</u> earch	<u>T</u> ermi	nal <u>F</u>	<u>H</u> elp								
[sysadmi	in@loca	lhost ~]\$	find	/etc	-size 10c	-ls 2>	/dev/n	ull				•	~
6399	4 - m	w-rr	1 r	oot	root		10 Nov	11	2010	/etc/sane.	d/sp	15c.	
conf												_	
137	0 lr	WXrWXrWX	1 r	oot	root		10 Nov	28	2012	/etc/rc4.d	->	rc.d	
/rc4.d													
134	0 lr	wxrwxrwx	1 r	oot	root		10 Nov	28	2012	/etc/rc1.d	->	rc.d	
/rcl.d													
139	0 lr	WXrWXrWX	1 r	oot	root		10 Nov	28	2012	/etc/rc6.d	->	rc.d	
/rc6.d	. 1												
135	0 lr	wxrwxrwx	1 r	00T	root		10 NOV	28	2012	/etc/rc2.d	->	rc.a	
/rc2.0	0.1-		1 -	t	reat		10 Nov	20	2012	(ata/raE d		ra d	
138 /rc5 d	υth	WXTWXTWX	T	001	root		TO NOV	28	2012	/etc/rcs.a	->	rc.a	
/1C5.0	4		1 0	oot	root		10 400	22	2010	/otc/socur	i+v/	conc	
ole anns	- + -i	w-rr α_util	1 1	001	1001		10 Aug	22	2010	/etc/secur	ILY/	cons	
5679	0 ln	yrwyrwy	1 n	oot	root		10 Nov	28	2012	/etc/rc0 d	->	rc d	
/rc0.d	0 11	WAT WAT WA	1 1	000	1000		10 1404	20	2012	/000/100.0		rc.u	
136	0 lr	wxrwxrwx	1 n	oot	root		10 Nov	28	2012	/etc/rc3.d	->	rc.d	
/rc3.d										,,,	-		
[sysadmi	in@loca	lhost ~]\$											
138 /rc5.d 6302 ole.apps 5679 /rc0.d 136 /rc3.d [sysadmi	0 ln 4 -n 5/confi 0 ln 0 ln in@loca	wxrwxrwx w-rr g-util wxrwxrwx wxrwxrwx uxrwxrwx lhost ~]\$	1 m 1 m 1 m 1 m	oot oot oot	root root root root		10 Nov 10 Aug 10 Nov 10 Nov	28 22 28 28	2012 2010 2012 2012	/etc/rc5.d /etc/secur /etc/rc0.d /etc/rc3.d	-> ity// -> ->	rc.d cons rc.d rc.d	

If you want to search for files that are larger than a specified size, you place a + character before the size. For example, the following will look for all files in the /usr directory structure that are over 100 megabytes in size:

sysadmin@localhost:~	_ 0	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
<pre>[sysadmin@localhost ~]\$ find /usr -size +100M -ls 2> /dev/null 574683 104652 -rw-rr 1 root root 107158256 Aug 7 11:06 /usr/shar s/oxygen/icon-theme.cache [sysadmin@localhost ~]\$</pre>	e/ico	on Â

To search for files that are smaller than a specified size, place a - character before the file size.

8.5.4 Additional Useful Search Options

Option	Meaning
- maxdepth	Allows the user to specify how deep in the directory structure to search. For example, - maxdepth 1 would mean only search the specified directory and its immediate subdirectories.
-group	Returns files owned by a specified group. For example, -group payroll would return files owned by the payroll group.
-iname	Returns files that match specified filename, but unlike -name, -iname is case insensitive. For example, -iname hosts would match files named hosts, Hosts, HOSTS, etc.
-mmin	Returns files that were modified based on modification time in minutes. For example, - mmin 10 would match files that were modified 10 minutes ago.
-type	Returns files that match file type. For example, -type f would return files that are regular files.
-user	Returns files owned by a specified user. For example, -user bob would return files owned by the bob user.

There are many search options. The following table illustrates a few of these options:

8.5.5 Using Multiple Options

If you use multiple options, they act as an "and", meaning for a match to occur, all of the criteria must match, not just one. For example, the following command will display all files in the /etc directory structure that are 10 bytes in size *and* are plain files:

```
sysadmin@localhost:~
Σ
                                                                                 _ _
<u>File Edit View Search Terminal Help</u>
[sysadmin@localhost ~]$ find /etc -size 10c -type f -ls 2> /dev/null
                                                    10 Nov 11 2010 /etc/sane.d/sp15c.
 6399
          4 -rw-r--r--
                         1 root
                                     root
conf
  6302
          4 -rw-r--r--
                         1 root
                                                    10 Aug 22 2010 /etc/security/cons
                                     root
ole.apps/config-util
[sysadmin@localhost ~]$
```

8.6 Viewing Files Using the less Command

While viewing small files with the cat command poses no problems, it is not an ideal choice for large files. The cat command doesn't provide any way to easily pause and restart the display, so the entire file contents are dumped to the screen.

For larger files, you will want to use a *pager* command to view the contents. Pager commands will display one page of data at a time, allowing you to move forward and backwards in the file by using movement keys.

There are two commonly used pager commands:

- The less command: This command provides a very advanced paging capability. It is normally the default pager used by commands like the man command.
- The more command: This command has been around since the early days of UNIX. While it has fewer features than the less command, it does have one important advantage: The less command isn't always included with all Linux distributions (and on some distributions, it isn't installed by default). The more command is always available.

When you use the more or less commands, they will allow you to "move around" a document by using *keystroke commands*. Because the developers of the less command based the command from the functionality of the more command, all of the keystroke commands available in themore command also work in the less command.

For the purpose of this manual, the focus will be on the more advanced command (less). Themore command is still useful to remember for times when the less command isn't available. Remember that most of the keystroke commands provided work for both commands.

8.6.1 Help Screen in less

When you view a file with the less command, you can use the **h** key to display a help screen. The help screen allows you to see which other commands are available. In the following example, the less /usr/share/dict/words command is executed. Once the document is displayed, the**h** key was pressed, displaying the help screen:

Σ					sy	sadmi	n@localhost:~	. 🗆	×
<u>F</u> ile	<u>E</u> dit	<u>V</u> iew	<u>S</u> ear	ch	<u>T</u> ermina	l <u>H</u> elp)		
									^
			S	SUMN	MARY OF	LESS (COMMANDS		
	Cor Not	mmands tes in	marke paren	ed w nthe	with * m eses ind	ay be licate	preceded by a number, <u>N</u> . the behavior if <u>N</u> is given.		
h	Н				Display	this	help.		
q	: q	Q :Q	ZZ		Exit.				
								-	
					MO	ING			
е	^E	i ^N	CR	*	Forward	one	line (or N lines).		Ξ
v	^Ÿ	k ^K	^P	*	Backwar	d one	line (or N lines).		
f	^F	^V SP	ACE	*	Forward	one	window (or <u>N</u> lines).		
b	^В	ESC-v		*	Backwar	d one	window (or <u>N</u> lines).		
Z				*	Forward	one	window (and set window to <u>N</u>).		
W				*	Backwar	d one	window (and set window to <u>N</u>).		
ES	C-SP/	ACE		*	Forward	l one	window, but don't stop at end-of-file.		
d	^D			*	Forward	one	half-window (and set half-window to \underline{N}).		
u	^U			*	Backwar	d one	half-window (and set half-window to \underline{N}).		
ES	C-)	RightA	rrow	*	Left d	ne ha	lf screen width (or <u>N</u> positions).		
ES	C - (LeftAr	row	*	Right o	ne ha	lf screen width (or <u>N</u> positions).		
HELP		Press R	RETURN	l fo	or more,	or q	when done		\sim

8.6.2 less Movement Commands

There are many movement commands for the less command, each with multiple possible keys or key combinations. While this may seem intimidating, remember you don't need to memorize all of these movement commands; you can always use the **h** key whenever you need to get help.

The first group of movement commands that you may want to focus upon are the ones that are most commonly used. To make this even easier to learn, the keys that are identical in more and less will be summarized. In this way, you will be learning how to move in more and less at the same time:

Movement	Кеу
Window forward	Spacebar
Window backward	b

Movement	Кеу
Line forward	Enter
Exit	q
Help	h

When simply using less as a pager, the easiest way to advance forward a page is to press the spacebar.

8.6.3 less Searching Commands

There are two ways to search in the less command: you can either search forward or backwards from your current position using patterns called regular expressions. More details regarding regular expressions are provided later in this chapter.

To start a search to look forward from your current position, use the *I* key. Then, type the text or pattern to match and press the **Enter** key.

If a match can be found, then your cursor will move in the document to the match. For example, in the following graphic the expression "frog" was searched for in the /usr/share/dict/words file:

Σ				sysa	admin@localhost:~	×
<u>F</u> ile	<u>E</u> dit	<u>V</u> iew	<u>S</u> earch	<u>T</u> erminal	<u>H</u> elp	
Afrog	aea					^
Afrog	aean					
afror	mosia	9				
afros	110310					
Afro-	semit	tic				
afrow	/n					
AFS						
AFSC						
AFSCM	1E					
Afsha	in Vr					
AFSK	11					Ξ
AFT						
aft						
aftab	a					
after						
after	·-					
after	-acqu	iirea				
after	acc					
after	atta	ck				
after	band					
:						~

Notice that "frog" didn't have to be a word by itself. Also notice that while the less command took you to the first match from the current position, all matches were highlighted.

If no matches forward from your current position can be found, then the last line of the screen will report "Pattern not found":

Pattern not found (press RETURN)

To start a search to look backwards from your current position, press the **?** key, then type the text or pattern to match and press the **Enter** key. Your cursor will move backward to the first match it can find or report that the pattern cannot be found.

¥

If more than one match can be found by a search, then using the **n** key will allow you to move to the next match and using the **N** key will allow you to go to a previous match.

8.7 Revisiting the head and tail Commands

Recall that the head and tail commands are used to filter files to show a limited number of lines. If you want to view a select number of lines from the top of the file, you use the head command and if you want to view a select number of lines at the bottom of a file, then you use the tail command.

By default, both commands display ten lines from the file. The following table provides some examples:

Command Example	Explanation of Displayed Text
head /etc/passwd	First ten lines of /etc/passwd
head -3 /etc/group	First three lines of /etc/group
head -n 3 /etc/group	First three lines of /etc/group
help head	First ten lines of output piped from the help command
tail /etc/group	Last ten lines of /etc/group
tail -5 /etc/passwd	Last five lines of /etc/passwd
tail -n 5 /etc/passwd	Last five lines of /etc/passwd
help tail	Last ten lines of output piped from the help command

As seen from the above examples, both commands will output text from either a regular file or from the output of any command sent through a pipe. They both use the -n option to indicate how many lines to output.

8.7.1 Negative Value with the -n Option

Traditionally in UNIX, the number of lines to output would be specified as an option with either command, so -3 meant show three lines. For the tail command, either -3 or -n -3 still means show three lines. However, the GNU version of the head command recognizes -n -3 as show all but the first three lines, and yet the head command still recognizes the option -3 as show the first three lines.

8.7.2 Positive Value With the tail Command

The GNU version of the tail command allows for a variation of how to specify the number of lines to be printed. If you use the -n option with a number prefixed by the plus sign, then the tail command recognizes this to mean to display the contents starting at the specified line and continuing all the way to the end.

For example, the following will display line #22 to the end of the output of the n1 command:

Σ	sysadmin@localhost:~ _ 🗆	×
<u>F</u> ile <u>E</u>	dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp	
[sysadn	nin@localhost ~]\$ nl /etc/passwd tail -n +22	^
22	<pre>saslauth:x:498:76:"Saslauthd user":/var/empty/saslauth:/sbin/nologin</pre>	
23	postfix:x:89:89::/var/spool/postfix:/sbin/nologin	
24	avahi:x:70:70:Avahi mDNS/DNS-SD Stack:/var/run/avahi-daemon:/sbin/nologin	1
25	haldaemon:x:68:68:HAL daemon:/:/sbin/nologin	
26	pulse:x:497:496:PulseAudio System Daemon:/var/run/pulse:/sbin/nologin	
27	gdm:x:42:42::/var/lib/gdm:/sbin/nologin	
28	rpcuser:x:29:29:RPC Service User:/var/lib/nfs:/sbin/nologin	
29	nfsnobody:x:65534:65534:Anonymous NFS User:/var/lib/nfs:/sbin/nologin	
30	abrt:x:173:173::/etc/abrt:/sbin/nologin	
31	sshd:x:74:74:Privilege-separated SSH:/var/empty/sshd:/sbin/nologin	
32	tcpdump:x:72:72::/:/sbin/nologin	
33	sysadmin:x:500:500:sysadmin:/home/sysadmin:/bin/bash	
34	mysql:x:27:27:MySQL Server:/var/lib/mysql:/bin/bash	
35	named:x:25:25:Named:/var/named:/sbin/nologin	
[cvcadn	nin@localhost ~l¢	

[sysadmin@localnost ~]\$

8.7.3 Following Changes to a File

You can view live file changes by using the -f option to the tail command. This is useful when you want to see changes to a file as they are happening.

A good example of this would be when viewing log files as a system administrator. Log files can be used to troubleshoot problems and administrators will often view them "interactively" with the tail command as they are performing the commands they are trying to troubleshoot in a separate window.

For example, if you were to log in as the root user, you could troubleshoot issues with the email server by viewing live changes to its log file with the following command: tail -f /var/log/mail.log

8.8 Sorting Files or Input

The sort command can be used to rearrange the lines of files or input in either dictionary or numeric order based upon the contents of one or more fields. Fields are determined by a field separator contained on each line, which defaults to whitespace (spaces and tabs).

The following example creates a small file, using the head command to grab the first 5 lines of the/etc/passwd file and send the output to a file called mypasswd.

daemon:x:1:1:daemon:/usr/sbin:/bin/sh
root:x:0:0:root:/root:/bin/bash
sync:x:4:65534:sync:/bin:/bin/sync
sys:x:3:3:sys:/dev:/bin/sh
sysadmin@localhost:~\$

8.8.1 Fields and Sort Options

In the event that the file or input might be separated by another delimiter like a comma or colon, the -t option will allow for another field separator to be specified. To specify fields to sort by, use the -k option with an argument to indicate the field number (starting with 1 for the first field).

The other commonly used options for the sort command are the -n to perform a numeric sort and -r to perform a reverse sort.

In the next example, the -t option is used to separate fields by a colon character and performs a numeric sort using the third field of each line:

	sysadmin@localhost:~	-	x
<u>F</u> ile	<u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysa root: bin:> daemo adm:> lp:x: [sysa	admin@localhost ~]\$ sort -t: -n -k3 mypasswd :x:0:0:root:/root:/bin/bash x:1:1:bin:/bin:/sbin/nologin on:x:2:2:daemon:/sbin:/sbin/nologin x:3:4:adm:/var/adm:/sbin/nologin :4:7:lp:/var/spool/lpd:/sbin/nologin admin@localhost ~]\$		<

Note that the -r option could have been used to reverse the sort, making the higher numbers in the third field appear at the top of the output:

Σ	sysadmin@localhost:~	_ 0	×
<u>File Edit V</u> iew	<u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@loca lp:x:4:7:lp:/va adm:x:3:4:adm:/ daemon:x:2:2:da bin:x:1:1:bin:/ root:x:0:0:root [sysadmin@loca	lhost ~]\$ sort -t: -n -r -k3 mypasswd ar/spool/lpd:/sbin/nologin ′var/adm:/sbin/nologin aemon:/sbin:/sbin/nologin /bin:/sbin/nologin t:/root:/bin/bash lhost ~]\$ ∎		<

Lastly, you may want to perform more complex sorts, such as sort by a primary field and then by a secondary field. For example, consider the following data:

bob:smith:23
nick:jones:56
sue:smith:67

You might want to sort first by the last name (field #2) and then first name (field #1) and then by age (field #3). This can be done with the following command:

```
sort -t: -k2 -k1 -k3n filename
```

8.9 Viewing File Statistics With the wc Command

The wc command allows for up to three statistics to be printed for each file provided, as well as the total of these statistics if more than one filename is provided. By default, the wc command provides the number of lines, words and bytes (1 byte = 1 character in a text file):

Σ	sysadmin@localhost:~	_	×
<u>F</u> ile	<u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysa	admin@localhost ~]\$ wc /etc/passwd /etc/passwd-		^
35	56 1710 /etc/passwd		
34	55 1665 /etc/passwd-		
69	111 3375 total		Ξ
[sysa	admin@localhost ~]\$		\sim

The above example shows the output from executing: wc /etc/passwd /etc/passwd-. The output has four columns: number of lines in the file, number of words in the file, number of bytes in the file and the file name or "total".

If you are interested in viewing just specific statistics, then you can use -1 to show just the number of lines, -w to show just the number of words and -c to show just the number of bytes.

The wc command can be useful for counting the number of lines output by some other command through a pipe. For example, if you wanted to know the total number of files in the /etc directory, you could execute ls /etc | wc -l:

Σ	sysadmin@localhost:~	_	×
<u>F</u> ile <u>E</u>	dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysad	nin@localhost ~]\$ ls /etc/ wc -l		^
254			Ξ
[sysadı	nin@localhost ~]\$		\sim

8.10 Using the cut Command to Filter File Contents

The cut command can extract columns of text from a file or standard input. A primary use of the cut command is for working with delimited database files. These files are very common on Linux systems.

By default, it considers its input to be separated by the **Tab** character, but the -d option can specify alternative delimiters such as the colon or comma.

Using the -f option, you can specify which fields to display, either as a hyphenated range or a comma separated list.

In the following example, the first, fifth, sixth and seventh fields from mypasswd database file are displayed:

📧 sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
<pre>[sysadmin@localhost ~]\$ cut -d: -f1,5-7 mypasswd root:root:/root:/bin/bash bin:bin:/bin:/sbin/nologin daemon:daemon:/sbin:/sbin/nologin adm:adm:/var/adm:/sbin/nologin lp:lp:/var/spool/lpd:/sbin/nologin [sysadmin@localhost ~]\$</pre>		

Using the cut command, you can also extract columns of text based upon character position with the -c option. This can be useful for extracting fields from fixed-width database files. For example, the following will display just the file type (character #1), permissions (characters #2-10) and filename (characters #50+) of the output of the ls -1 command:

sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
<pre>[sysadmin@localhost ~]\$ ls -l cut -cl-11,50- total 36 drwxr-xr-x. Desktop drwxr-xr-x. Documents drwxr-xr-x. Downloads drwxr-xr-x. Music -rw-rw-r mypasswd drwxr-xr-x. Pictures drwxr-xr-x. Pictures drwxr-xr-x. Templates drwxr-xr-x. Videos [sysadmin@localhost ~]\$</pre>		<

8.11 Using the grep Command to Filter File Contents

The grep command can be used to filter lines in a file or the output of another command based on matching a pattern. That pattern can be as simple as the exact text that you want to match or it can be much more advanced through the use of regular expressions (discussed later in this chapter).

For example, you may want to find all the users who can login to the system with the BASH shell, so you could use the grep command to filter the lines from the /etc/passwd file for the lines containing the characters "bash":

	~
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp	
[sysadmin@localhost ~]\$ grep bash /etc/passwd root:x:0:0:root:/root:/bin/bash sysadmin:x:500:500:sysadmin:/bamo/sysadmin:/bin/bash	^
mysql:x:27:27:MySQL Server:/var/lib/mysql:/bin/bash	Ξ

To make it easier to see what exactly is matched, use the --color option. This option will highlight the matched items in red:

E	sysadmin@localhost:~	-	×
<u>File E</u> dit <u>V</u> ie	w <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@loc root:x:0:0:ro sysadmin:x:50 mysql:x:27:27 [sysadmin@loc	alhost ~]\$ grepcolor bash /etc/passwd ot:/root:/bin/ <mark>bash</mark> 0:500:sysadmin:/home/sysadmin:/bin/ <mark>bash</mark> :MySQL Server:/var/lib/mysql:/bin/ <mark>bash</mark> alhost ~]\$		^

In some cases you don't care about the specific lines that match the pattern, but rather how many lines match the pattern. With the -c option, you can get a count of how many lines that match:

When you are viewing the output from the grep command, it can be hard to determine the original line numbers. This information can be useful when you go back into the file (perhaps to edit the file) as you can use this information to quickly find one of the matched lines.

The -n option to the grep command will display original line numbers:

	sysadmin@localhost:~	_	×
<u>F</u> ile	<u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sys 1:ro 33:s 34:m [sys	admin@localhost ~]\$ grep -n bash /etc/passwd ot:x:0:0:root:/root:/bin/bash ysadmin:x:500:500:sysadmin:/home/sysadmin:/bin/bash ysql:x:27:27:MySQL Server:/var/lib/mysql:/bin/bash admin@localhost ~]\$		^

Some additional useful grep options:

Examples	Output
grep -v nologin /etc/passwd	All lines not containing "nologin" in the /etc/passwd file
grep -l linux /etc/*	List of files in the /etc directory containing "linux"
grep -i linux /etc/*	Listing of lines from files in the /etc directory containing any case (capital or lower) of the character pattern "linux"
grep -w linux /etc/*	Listing of lines from files in the /etc directory containing the word pattern "linux"

8.12 Basic Regular Expressions

A *Regular Expression* is a collection of "normal" and "special" characters that are used to match simple or complex patterns. Normal characters are alphanumeric characters which match themselves. For example, an "a" would match an "a".

Some characters have special meanings when used within patterns by commands like the grep command. There are both *Basic Regular Expressions* (available to a wide variety of Linux commands) and *Extended Regular Expressions* (available to more advanced Linux commands). Basic Regular Expressions include the following:

Regular Expression	Matches
	Any single character
[]	A list or range of characters to match one character, unless the first character is the caret "^", and then it means any character not in the list
*	Previous character repeated zero or more times
۸	Following text must appear at beginning of line
\$	Preceding text must appear at the end of the line

The grep command is just one of many commands that support regular expressions. Some other commands include the more and less commands. While some of the regular expressions are unnecessarily quoted with single quotes, it is a good practice to use single quotes around your regular expressions to prevent the shell from trying to interpret special meaning from them.

8.12.1 Basic Regular Expressions - the . Character

In the example below, a simple file is first created using redirection. Then the grep command is used to demonstrate a simple pattern match:

sysadmin@localhost:~	_ = ×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp	
[sysadmin@localhost ~]\$ echo 'abcddd' > example.txt [sysadmin@localhost ~]\$ cat example.txt abcddd	6
[sysadmin@localhost ~]\$ grepcolor 'a' example.txt abcddd [sysadmin@localhost ~]\$	

In the previous example, you can see that the pattern "a.." matched "abc". The first . character matched the "b" and the second matched the "c".

In the next example, the pattern "a..c" won't match anything, so the grep command will not product any output. For the match to be successful, there would need to be two characters between the "a" and the "c":

sysadmin@localhost:~	_ = ×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp	
[sysadmin@localhost ~]\$ grepcolor 'ac' example.txt [sysadmin@localhost ~]\$	

8.12.2 Basic Regular Expressions - the [] Characters

If you use the . character, then any possible character could match. In some cases you want to specify exactly which characters you want to match. For example, maybe you just want to match a lower-case alpha character or a number character. For this, you can use the [] Regular Expression characters and specify the valid characters inside the [] characters.

For example, the following command matches two characters, the first is either an "a" or a "b" while the second is either an "a", "b", "c" or "d":

📧 sysadmin@localhost:~	_ = ×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp	
[sysadmin@localhost ~]\$ grepcolor '[ab][a-d]' example.txt abcddd [sysadmin@localhost ~]\$	<u>^</u>

Note that you can either list out each possible character ([abcd]) or provide a range ([a-d]) as long as the range is in the correct order. For example, [d-a] wouldn't work because it isn't a valid range:

📧 sysadmin@localhost:~	_	o x
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ grepcolor '[d-a]' example.txt grep: Invalid range end [sysadmin@localhost ~]\$		^

The range is specified by a standard called the ASCII table. This table is a collection of all printable characters in a specific order. You can see the ASCII table with the man ascii command. A small example:

041	33	21	!	141	97	61	а
042	34	22	н	142	98	62	b
043	35	23	#	143	99	63	С
044	36	24	\$	144	100	64	d
045	37	25	%	145	101	65	e
046	38	26	&	146	102	66	f

Since "a" has a smaller numeric value (141) then "d" (144), the range a-d includes all characters from "a" to "d".

What if you want to match a character that can be anything but an "x", "y" or "z"? You wouldn't want to have to provide a [] set with all of the characters except "x", "y" or "z".

To indicate that you want to match a character that is not one of the listed characters, start your [] set with a ^ symbol. For example, the following will demonstrate matching a pattern that includes a character that isn't an "a", "b" or "c" followed by a "d":

sysadmin@localhost:~	_ = ×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp	
[sysadmin@localhost ~]\$ grepcolor '[^abc]d' example.txt abc <mark>dd</mark> d [sysadmin@localhost ~]\$	<u></u>

8.12.3 Basic Regular Expressions - the * Character

The * character can be used to match "zero or more of the previous character". For example, the following will match zero or more "d" characters:

Σ	sysadmin@localhost:~	>	¢
<u>F</u> ile <u>E</u>	dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadn abc <mark>ddd</mark> [sysadn	nin@localhost ~]\$ grepcolor 'd*' example.txt nin@localhost ~]\$		^

8.12.4 Basic Regular Expressions - the ^ and \$ Characters

When you perform a pattern match, the match could occur anywhere on the line. You may want to specify that the match occurs at the beginning of the line or the end of the line. To match at the beginning of the line, begin the pattern with a ^ symbol.

In the following example, another line is added to the example.txt file to demonstrate the use of the ^ symbol:

Note that in the first grep output, both lines match because they both contain the letter "a". In the second grep output, only the line that began with the letter "a" matched.

In order to specify the match occurs at the end of line, end the pattern with the \$ character. For example, in order to only find lines which end with the letter "c":

8.12.5 Basic Regular Expressions - the $\$ Character

In some cases you may want to match a character that happens to be a special Regular Expression character. For example, consider the following:

sysadmin@localhost:~	-	×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp		
[sysadmin@localhost ~]\$ echo "abcd*" >> example.txt [sysadmin@localhost ~]\$ cat example.txt abcddd xyzabc abcd*		^
[sysadmin@localhost ~]\$ grepcolor "cd*" example.txt abcddd xyzabc abcd* [sysadmin@localhost ~]\$		

In the output of the grep command above, you will see that every line matches because you are looking for a 'c' character followed by zero or more 'd' characters". If you want to look for an actual * character, place a \ character before the * character:

🗉 sysadmin@localhost:~	_ 0 ×
<u>File Edit View Search Terminal H</u> elp	
[sysadmin@localhost ~]\$ grepcolor "cd*" example.txt ab <mark>cd</mark> *	^
[sysadmin@localhost ~]\$	

8.13 Extended Regular Expressions

The use of Extended Regular Expressions often requires a special option be provided to the command to recognize them. Historically, there is a command called egrep, which is similar to grep, but is able to understand their usage. Now, the egrep command is deprecated in favor of using grep with the -E option.

The following regular expressions are considered "extended":

RE	Meaning
?	Matches previous character zero or one time, so it is an optional character

+ Matches previous character repeated one or more times

Alternation or like a logical or operator

Some extended regular expressions examples:

Command	Meaning	Matches
grep -E 'colou?r' 2.txt	Match 'colo' following by zero or one 'u' character	color colour
grep -E 'd+' 2.txt	Match one or more 'd' characters	d dd ddd dddd
grep -E 'gray grey' 2.txt	Match either 'gray' or 'grey'	gray grey

8.14 xargs Command

If you receive an error about an argument list being too long when trying to execute a command, then it's probably time to think about using xargs with that command. The xargs command also has a useful option -0 that helps to eliminate problems with files that have spaces or tabs in their names.

The xargs command is useful for allowing commands to be executed more efficiently. Its goal is to build the command line for a command to execute as few as times as possible with as many arguments as possible, rather than to execute the command many times with one argument each time.

The following example shows a scenario where the xargs command allowed for many files to be removed, where using a normal wildcard (glob) character failed:

sysadmin@localhost:~/many	_ = ×
<u>F</u> ile <u>E</u> dit <u>V</u> iew <u>S</u> earch <u>T</u> erminal <u>H</u> elp	
[sysadmin@localhost many]\$ rm * bash: /bin/rm: Argument list too long [sysadmin@localhost many]\$ ls xargs rm [sysadmin@localhost many]\$
